Diglycosylated 1,2-diols as mimetics of sialyl-Lewis X and sialyl-Lewis A.

The present invention relates to mimetics of sialyl-Lewis X and sialyl-Lewis A, in which, in the natural tetrasaccharide, the neuraminic acid residue is replaced by an S-configured methyl substituted with one carboxyl residue and one other substituent and the N-acetyl-glucosamine residue is replaced by a non-glycosidic residue of a 1,2-diol, to processes for the preparation of these compounds and to the use of these mimetics in therapeutic methods.

The complex process of inflammation, which takes place in several stages, is the body's natural reaction to injuries in which, for example, there is also invasion by infectious agents. Under the influence of cytokines, the endothelium which lines the blood vessels expresses adhesion proteins on its surface. The P and E selectins bring about, by a protein-carbohydrate interaction with glycolipids and glycoproteins on the leukocyte membrane, the so-called "rolling" of leukocytes. The latter are slowed down by this process, and there is activation of certain proteins (integrins) on their surface which ensure firm adhesion of the leukocytes to the endothelium. This is followed by migration of the leukocytes into the damaged tissue.

When this process takes place in a controlled manner, the damage is eliminated after a certain time without major adverse effects remaining. It is otherwise in the case of certain acute and chronic inflammatory processes, in which the migration of leukocytes takes place in an uncontrolled manner, which leads to severe damage to the body. This is the case in disorders such as cardiogenic shock, myocardial infarct, thrombosis, rheumatism, psoriasis, dermatitis, acute respiratory distress syndrome and metastatic cancer [Dasgupta, F., Rao, B.N.N., Exp. Opin. Invest. Drugs 3:709-724 (1994)].

Several approaches to the development of medicaments which intervene at various points in these unwanted processes have already been pursued [Dasgupta, F., Rao, B.N.N., Exp. Opin. Invest. Drugs 3:709-724 (1994)]. The aim of one route is to prevent the interaction between P and E selectins and their receptors on the leukocyte membrane, thus to prevent the "rolling", by mimetics of the corresponding epitopes. This also results in suppression of

the subsequent processes. One of the smallest carbohydrate epitopes as ligand for E selectin is sialyl-Lewis X [neuraminic acid- $\alpha(2\rightarrow3)$ -galactose- $\beta(1\rightarrow4)$ -(fucose- $\alpha(1\rightarrow3)$ )-N-acetylglucosamine (sLe<sup>x</sup>)].

EP-A-0 579 196 proposed as compounds competing with the natural ligands for binding to E selectin mimetics of sLe<sup>x</sup> in which the neuraminic acid residue is replaced by a lactic acid residue. WO 93/10796 describes compounds which comprise in place of the neuraminic acid residue the residue of an  $\alpha$ -hydroxy acid. WO 93/23031 discloses mimetics in which the N-acetylglucosamine residue (GlcNAc residue) is replaced by an R,R-1,2-cyclohexanedioxy. However, it is common to all these compounds that the binding affinity between them and the E selectin is increased only inconsiderably compared with that of sLe<sup>x</sup>, or is in fact worse, and is insufficient for a therapeutic effect.

It has now been found, surprisingly, that simultaneous replacement of the neuraminic acid residue by an S-configured methyl substituted with one carboxyl residue and one other substituent and of the N-acetylglucosamine residue by a non-glycosidic residue of an aliphatic diol results in an unexpectedly high binding affinity of the resulting mimetic. The novel compounds additionally represent a structural and chemical simplification, have a lower molecular weight and can be obtained in larger quantities by methods with low synthetic complexity.

The present invention relates to compounds of the formula I

For the purposes of the present invention, a metal is to be understood as meaning an alkali metal [for example lithium (Li), sodium (Na), potassium (K), rubidium (Rb) and caesium (Cs)], an alkaline earth metal [for example magnesium (Mg), calcium (Ca) and strontium (Sr)] or manganese (Mn), iron (Fe), zinc (Zn) or silver (Ag). Physiologically tolerated salts are to be understood as meaning, in particular, the alkali metal and alkaline earth metal salts, for example sodium, potassium, magnesium and calcium salts. Sodium and potassium ions and their salts are preferred.

Halogen is to be understood as meaning a representative of the group consisting of fluorine, chlorine, bromine and iodine. Fluorine, chlorine and bromine are preferred, especially fluorine and chlorine.

Alkyl can be linear or branched, preferably branched once or twice in the  $\alpha$  position. The present invention additionally relates to a process for the preparation of the compounds of the formula I which comprises etherifying the 3-OH group of a compound of the formula V

in which  $\text{R}_2$  and  $\text{X}$  have the abovementioned meanings,  $\text{R}_{12}$  is a protective group and  $\text{R}_{12}'$  and  $\text{R}_{12}''$  are, independently of one another, hydrogen or a protective group, with a compound of the formula VI

in which  $\text{R}_1$  has the abovementioned meaning and  $\text{R}_{13}$  is a leaving group, and eliminating the protective groups.

Leaving groups can be: halides, such as chloride, bromide and iodide, and sulfonic acids, for example trifluoromethanesulfonate, aliphatic, cycloaliphatic or aromatic sulfonic acids which are unsubstituted or substituted by C<sub>1</sub>-C<sub>4</sub>alkyl; C<sub>1</sub>-C<sub>4</sub>alkoxy, nitro, cyano or halogen (chlorine, bromine). Some examples of these acids are: methanesulfonic acid, mono-, di- or trifluoromethanesulfonic acids or p-nitrobenzenesulfonic acid. CF<sub>3</sub>-SO<sub>2</sub>-O<sup>-</sup> (also referred to as triflate) is particularly preferably used. The leaving group is advantageously selected from the group consisting of halogen and unsubstituted and halogenated R-SO<sub>2</sub>-, in which R is C<sub>1</sub>-C<sub>12</sub>alkyl, in particular C<sub>1</sub>-C<sub>6</sub>alkyl, C<sub>5</sub>-C<sub>6</sub>cycloalkyl, phenyl, benzyl, C<sub>1</sub>-C<sub>12</sub>alkylphenyl, in particular C<sub>1</sub>-C<sub>4</sub>alkylphenyl, or C<sub>1</sub>-C<sub>12</sub>alkylbenzyl, in particular C<sub>1</sub>-C<sub>4</sub>alkylbenzyl, for example methane, ethane, propane, butane, benzene, benzyl- and p-methylbenzenesulfonyl. Preferred leaving groups are Cl, Br, I, -SO<sub>2</sub>CF<sub>3</sub> (triflate) and p-nitrobenzenesulfonyl, and -SO<sub>2</sub>CF<sub>3</sub> is particularly preferred.

The compounds of the formula VI are known in some cases or can be obtained by known processes, as described by Degerbeck et al. [Degerbeck, F., Fransson, B., Grehn, L., Ragnarsson, U., J. Chem. Soc. Perkin Trans. 1:11-14 (1993)] and by Dureault et al. [Dureault, A., Tranchepain, I., Depezay, J.C., Synthesis 491-493 (1987)]. Optically pure compounds can be obtained by using optically pure starting compounds (e.g. amino acids, α-hydroxylic acids) or by chromatographic separation processes, for example with chiral solid phases.

The compounds of the formula V are novel and the invention likewise relates to them. They can be obtained by known glycosylation methods starting from known fucosyl and galactosyl donors and diols of the formula HO-X-OH. Stepwise introduction of galactose and fucose or vice versa is advantageous.

For the preparation of the compounds of the formula V, firstly the pseudo-trisaccharide building blocks are synthesized. The pseudotrisaccharide is assembled either by glycosidic attachment for the activated and protected galactose onto the fucose-O-X-OH building block or by glycosidic attachment of suitably protected and activated fucose onto a galactose-O-X-OH building block. Glycosylation reactions are known on a large scale and are described in the specialist literature.

It is then possible to introduce the group  $R_1$  into the pseudotrisaccharide. The resulting compounds of the formula I can subsequently be modified. This modification may comprise hydrogenation of aromatic compounds to cycloaliphatic groups, which can take place, for example, at the same time as the hydrogenolytic elimination of protective groups. It is furthermore possible for an amino group to be acylated and/or alkylated and/or sulfonated. The preparation of secondary and tertiary amines can be carried out by reductive amination.

It has proved advantageous to activate the 3-OH group of the galactose residue by etherification. Particularly suitable for this purpose are dialkyltin oxides, dialkyltin alkoxylates and bis(trialkyl)tin oxides. Some examples are dibutyltin oxide, dibutyltin(O-methyl)<sub>2</sub> and (tributyltin)<sub>2</sub>O. The activating agents are preferably used in stoichiometric amounts. In this case, the reaction is carried out in two stages, namely a) activation and b) coupling with the compounds of the formula VI.

The activation process can be carried out at temperatures from 40 to 200°C, preferably 60 to 120°C.

The compounds of the formula V and of the formula VI can be employed in equimolar amounts. However, it has proved expedient to employ the compounds of the formula VI in excess, for example in an amount which is up to 10 times, preferably up to 5 times, the amount of the compound of the formula V.

It is furthermore expedient to carry out the reaction in both reaction stages in the presence of an inert solvent or mixtures of solvents. Reactive protic solvents such as alkanols and, furthermore, acid amides are unsuitable in reaction stage b). It is possible to use non-polar aprotic and polar aprotic or polar protic solvents. These may be aliphatic or aromatic hydrocarbons such as pentane, hexane, cyclohexane, methylcyclohexane, benzene, toluene or xylene, halogenated hydrocarbons such as methylene chloride, chloroform, tetrachloromethane, 1,2-dichloroethane, 1,1,2-trichloroethane, 1,1,2,2-tetrachloroethane and chlorobenzene, linear or cyclic ethers such as diethyl ether, dibutyl ether, ethylene glycol dimethyl or diethyl ether, tetrahydrofuran and dioxane, N,N-dialkylated carboxamides such as dimethylformamide, N-alkylated lactams such as N-methylpyrrolidone, ketones such as acetone and methyl isobutyl ketone, carboxylic esters such as methyl or ethyl acetate, or

alkanols such as methanol, ethanol, propanol, butanol and ethylene glycol monoethyl ether. Particularly preferred solvents are methanol, ethanol, benzene and toluene.

Protective groups and processes for derivatizing hydroxyl groups with such protective groups are generally known in sugar and nucleotide chemistry and are described, for example, by Beaucage, S.L. Iyer, R., *Tetrahedron* 48:2223-2311 (1992). Examples of such protective groups are: benzyl, methylbenzyl, dimethylbenzyl, methoxybenzyl, dimethoxybenzyl, bromobenzyl, 2,4-dichlorobenzyl; diphenylmethyl, di(methylphenyl)methyl, di(di-methylphenyl)methyl, di(methoxyphenyl)methyl, di(dimethoxyphenyl)methyl, triphenylmethyl, tris-4,4',4''-tert-butylphenylmethyl, di-p-anisylphenylmethyl, tri(methylphenyl)methyl, tri(dimethylphenyl)methyl, methoxyphenyl(diphenyl)methyl, di(methoxyphenyl)phenylmethyl, tri(methoxyphenyl)methyl, tri(dimethoxyphenyl)methyl; triphenylsilyl, alkyl-diphenylsilyl, dialkylphenylsilyl and trialkylsilyl with 1 to 20, preferably 1 to 12, and particularly preferably 1 to 8 C atoms in the alkyl groups, for example triethylsilyl, tri-n-propylsilyl, i-propyl-dimethylsilyl, t-butyl-dimethylsilyl, t-butyl-diphenylsilyl, n-octyl-dimethylsilyl, (1,1,2,2-tetramethylethyl)dimethylsilyl; C<sub>2</sub>-C<sub>12</sub>-, in particular C<sub>2</sub>-C<sub>8</sub>acyl, such as acetyl, propanoyl, butanoyl, pentanoyl, hexanoyl, benzoyl, methylbenzoyl, methoxybenzoyl, chlorobenzoyl and bromobenzoyl. The protective groups can be identical or different. Preferred protective groups are selected from the group consisting of linear and branched C<sub>1</sub>-C<sub>8</sub>alkyl, in particular C<sub>1</sub>-C<sub>4</sub>alkyl, for example methyl, ethyl, n- and i-propyl, n-, i- and t-butyl; C<sub>7</sub>-C<sub>12</sub>aralkyl, for example benzyl; trialkylsilyl with 3 to 20 C atoms, in particular 3 to 12 C atoms, for example triethylsilyl, tri-n-propylsilyl, tri-i-propylsilyl, i-propyl-dimethylsilyl, t-butyl-dimethylsilyl, t-butyl-diphenylsilyl, n-octyl-dimethylsilyl, (1,1,2,2-tetramethylethyl)dimethylsilyl; substituted methyldene groups which are obtainable by acetal or ketal formation from adjacent hydroxyl groups of the sugars or sugar derivatives with aldehydes and ketones, which preferably contain 2 to 12 or 3 to 12 C atoms, for example C<sub>1</sub>-C<sub>12</sub>alkylidene, preferably C<sub>1</sub>-C<sub>6</sub>alkylidene and in particular C<sub>1</sub>-C<sub>4</sub>alkylidene, such as ethylidene, 1,1- and 2,2-propylidene, 1,1- and 2,2-butylidene, benzylidene; unsubstituted and halogenated C<sub>2</sub>-C<sub>12</sub>acyl, in particular C<sub>2</sub>-C<sub>8</sub>acyl, such as acetyl, propanoyl, butanoyl, pentanoyl, hexanoyl, pivaloyl and benzoyl.

The synthesis preferably takes place with protective groups for R<sub>12</sub>' and R<sub>12</sub>'' which together form an alkylidene group with, preferably 1 to 12 and, more preferably 1 to 8 C atoms. In this connection, particularly preferred protective groups are those in which R<sub>12</sub>' and R<sub>12</sub>'' together are an alkylidene group with, in particular, 1 to 12 C atoms, with the alkylidene group

forming an acetal or ketal with the oxygen atoms. These protective groups are ones which can be eliminated under neutral or weakly acidic conditions. Particularly suitable protective groups are acyl, benzyl, substituted benzyl, benzyloxymethyl, alkyl and silyl.  $R_{12}'$  and  $R_{12}''$  are, particularly preferably, together alkylidene, for example alkyl- or alkoxy- substituted benzyldiene.  $R_{12}'$  and  $R_{12}''$  can, however, also be hydrogen, or one of  $R_{12}'$  and  $R_{12}''$  can be a protective group such as benzyl and the other one of  $R_{12}'$  and  $R_{12}''$  can be hydrogen.

Examples of protective carboxylate groups are alkoxy- and aralkoxycarbonyl groups, preferably  $-\text{CO}_2\text{Bn}$ ,  $-\text{CO}_2\text{CH}_3$ .

The reaction for elimination of the protective groups is preferably carried out at a temperature of  $0^\circ\text{C}$  to  $50^\circ\text{C}$ , and particular at room temperature.

Further details of the preparation of the compounds of the formula I are described in the examples.

An alternative synthetic route comprises glycosidic linkage of the protected fucose hydroxy ether of the formula VII

in which  $R_2$ ,  $R_{12}$  and  $X$  have the abovementioned meanings, with the protected galactose of the formula VIII

in which  $R_1$  has the abovementioned meaning, Z is O or S,  $R_{12}$  is a protective group and R is a leaving group, and subsequent removal of the protective groups from the resulting compound.

It is possible to choose reaction conditions like those implemented for the process described previously. The leaving group R can be, for example,  $-C(=NH)-CCl_3$  or 4-pentenyl. The compounds of the formula VII can be obtained in a simple manner by glycosidic linkage of appropriately protected fucose with a compound of the formula  $HO-X-OH$  which is monoprotected where appropriate. The compounds of the formula VIII can be obtained by etherification of compounds of the formula  $R_1OH$  with galactose which is protected where appropriate.

The compounds according to the invention have antiinflammatory properties and can accordingly be used as medicaments. It is possible with them in particular to alleviate disorders such as cardiogenic shock, myocardial infarct, thrombosis, rheumatism, psoriasis, dermatitis, acute respiratory distress syndrome, asthma, arthritis and metastatic cancer. The invention furthermore relates to the compounds according to the invention for use in a therapeutic method for the treatment of disorders in warm-blooded animals, including humans. The dosage on administration to warm-blooded animals with a body weight of about 70 kg can be, for example, 0.01 to 1000 mg per day. Administration preferably takes place in the form of pharmaceutical compositions, parenterally, for example intravenously or intraperitoneally.

The invention furthermore relates to a pharmaceutical composition comprising an effective amount of the compound according to the invention, alone or together with other active substances, a pharmaceutical carrier, preferably in a significant amount, and, where appropriate, excipients.

The pharmacologically active compounds according to the invention can be used in the form of compositions which can be administered parenterally or of infusion solutions. Solutions of this type are preferably isotonic aqueous solutions or suspensions, it being possible to prepare the latter, for example in the case of lyophilized compositions which comprise the active substance alone or together with a carrier, for example mannitol, before use. The pharmaceutical compositions can be sterilized and/or comprise excipients, for example pre-

servatives, stabilizers, wetting agents and/or emulsifiers, solubilizers, salts to control the osmotic pressure and/or buffers. The pharmaceutical compositions, which may, if required, comprise other pharmacologically active substances such as antibiotics, are produced in a manner known per se, for example by conventional dissolving or lyophilizing processes, and comprise about 0.1 % to 90 %, in particular from about 0.5 % to about 30 %, for example 1 to 5 %, of active substance(s).

The following examples illustrate the invention.

The crude product (1 g) is purified by flash chromatography on silica gel (ethyl acetate/hexane 1:4), resulting in benzyl *R*-3-azido-2-hydroxypropionate **29** (0.717 g, 85 %) as an oil.  $^1\text{H}$  NMR (250 MHz,  $\text{CDCl}_3$ )  $\delta$  7.36 (m, 5H), 5.25 (s, 2H), 4.39 (q,  $J=4.2$  Hz, 1H), 3.65 (dd,  $J=3.3, 12.9$  Hz, 1H), 3.51 (dd,  $J=4.3, 12.9$  Hz, 1H), 3.20 (d,  $J=4.0$  Hz, 1H).

Trifluoromethanesulfonic anhydride (770 ml, 4.41 mmol) is added at  $-20^\circ\text{C}$  with stirring to a solution of the alcohol **29** (0.85 g, 3.84 mmol) and 2,6-di-*tert*-butylpyridine (1.12 ml, 4.99 mmol) in dry  $\text{CH}_2\text{Cl}_2$  (11.0 ml). The clear colourless solution is warmed to  $0^\circ\text{C}$  over the course of 40 minutes and is stirred at this temperature for a further 2 hours. The mixture is diluted with  $\text{CH}_2\text{Cl}_2$  (40 ml) and, while stirring vigorously, 1 M aqueous  $\text{KH}_2\text{PO}_4$  solution (30 ml) is added. The organic phase is separated off and the aqueous phase is extracted twice with  $\text{CH}_2\text{Cl}_2$ . The combined organic phases are washed with  $\text{H}_2\text{O}$  (30 ml), dried ( $\text{Na}_2\text{SO}_4$ ), filtered and concentrated in vacuo. The oily residue (2.3 g) is purified by flash chromatography on a short silica gel column (ethyl acetate/hexane 1:7), resulting in the benzyl *R*-3-azido-2-trifluoromethanesulfonyloxypropionate **A1** (1.16 g, 85 %) as a yellowish oil.  $^1\text{H}$  NMR (250 MHz,  $\text{CDCl}_3$ )  $\delta$  7.38 (br s, 5H), 5.32 (d,  $J=12.1$  Hz, 1H), 5.27 (d,  $J=12.1$  Hz, 1H), 5.24 (dd,  $J=4.2, 5.5$  Hz, 1H), 3.90 - 3.75 (m, 2H);  $^{13}\text{C}$  NMR (63 MHz,  $\text{CDCl}_3$ )  $\delta$  164.4, 133.9, 129.1, 128.8, 128.6, 120.9, 81.0, 69.0, 51.5.

The solution is concentrated in vacuo and azeotroped first with ethanol and then with hexane, subsequently dried under high vacuum in order to remove remaining H<sub>2</sub>O. The residue is mixed with N,N-dimethylformamide (1.3 ml) and benzyl bromide (132  $\mu$ l, 1.11 mmol), and the mixture is stirred at room temperature for 75 minutes. Then trifluoromethanesulfonic anhydride (222  $\mu$ l, 1.27 mmol) is added dropwise over the course of 3 minutes, and the solution is warmed to 0°C over the course of 45 minutes. After 75 minutes at 0°C, the mixture is diluted with CH<sub>2</sub>Cl<sub>2</sub> (20 ml) and washed with 1 molar aqueous KH<sub>2</sub>PO<sub>4</sub> solution (15 ml). The aqueous phase is extracted with CH<sub>2</sub>Cl<sub>2</sub> (2 x 10 ml), and the combined organic phases are washed with H<sub>2</sub>O (10 ml), dried (Na<sub>2</sub>SO<sub>4</sub>), filtered and concentrated in vacuo. Chem. 38:1538-1546 (1995)] and of the acceptor 2 (3.44 g, 6.46 mmol) is dried under high vacuum for one hour. Then activated 4Å molecular sieves (20 g) and DMTST (4.17 g, 16.14 mmol) are added under a nitrogen atmosphere, followed by  $\text{CH}_2\text{Cl}_2$  (70 ml). The yellowish suspension is dried at room temperature and, after 3 hours, 5 ml of a suspension consisting of DMTST (5.84 g, 22.61 mmol), 4Å molecular sieves (4.0 g) and  $\text{CH}_2\text{Cl}_2$  (35 ml) are added. Further 5 ml portions of this DMTST suspension are added after 30, 45 and 90 minutes respectively. The brown reaction mixture is then stirred for 15 hours, and thereafter filtered through Hyflo Super Cel® (filter aid), washing with  $\text{CH}_2\text{Cl}_2$  (300 ml). The filtrate is extracted by shaking first with 10 % aqueous  $\text{NaHCO}_3$  solution and then with saturated  $\text{NaCl}$  solution, and the organic phase is dried with  $\text{Na}_2\text{SO}_4$ , filtered and concentrated in a vacuum rotary evaporator. A mixture of the tetrol 4 (0.038 g, 0.055 mmol) and di-*n*-butyltin oxide (0.029 g, 0.117 mmol) in dry methanol (2.0 ml) is heated under reflux in an argon atmosphere. After 2.25 hours, the clear, colourless solution is concentrated in vacuo, and the residue is mixed with benzene and concentrated several times in order to remove excess MeOH. It is then dried under high vacuum for 30 minutes, and the residue is mixed under an argon atmosphere with CsF (dried under high vacuum at 300°C, 0.03 g, 0.197 mmol) and dry 1,2-dimethoxyethane (0.4 ml). The mixture is cooled to 0°C, and a solution of benzyl R-3-phenyl-2-trifluoromethanesulfonyloxypropionate [Degerbeck, F., Fransson, B., Grehn, L., Ragnarsson, U., J. Chem. Soc. Perkin Trans. 1:11-14 (1993)] (0.085 g, 0.219 mmol) in dry 1,2-dimethoxyethane (0.4 ml) is added using a syringe. The reaction mixture is then warmed to room temperature and stirred for one hour, after which it is stirred at 40°C for a further 2 hours. After addition of aqueous 1M  $\text{KH}_2\text{PO}_4$  solution, the mixture is diluted with water and extracted three times with  $\text{CH}_2\text{Cl}_2$ . The combined organic phases are washed with aqueous KF solution and then dried ( $\text{Na}_2\text{SO}_4$ ), filtered and concentrated in vacuo. Purification of the residue takes place by flash chromatography twice on silica gel (first chromatography: 2 %

A suspension of **13** (0.086 g, 0.11 mmol) and di-*n*-butyltin oxide (0.05 g, 0.19 mmol) in dry benzene (3.3 ml) is boiled under reflux in an argon atmosphere for 12 hours. The reaction mixture is concentrated in vacuo and dried under high vacuum for one hour. Then CsF (dried under high vacuum at 300°C for several hours, 0.042 g, 0.274 mmol) is added under an argon atmosphere, followed by dry 1,2-dimethoxyethane (0.6 ml) and a solution of triflate **A3** (0.25 g, 0.66 mmol) in dry 1,2-dimethoxyethane (0.4 ml). The reaction mixture is heated to 35 to 40°C and stirred at this temperature for 5 hours. Then a solution of 15% KF in 1M aqueous KH<sub>2</sub>PO<sub>4</sub> solution (30 ml) is added, and the mixture is extracted three times with CH<sub>2</sub>Cl<sub>2</sub>, and the combined organic phases are dried (Na<sub>2</sub>SO<sub>4</sub>), filtered and concentrated in vacuo. The oily residue (0.16 g) is purified by column chromatography on silica gel (gradient elution: toluene/ethyl acetate 80:20 to 75:25, then CH<sub>2</sub>Cl<sub>2</sub>/MeOH 19:1), resulting in the ether **31** (0.049 g, 44 %) as a colourless foam and the precursor **13** (0.035 g, 40 %).

Dioxane (2.0 ml), water (1.0 ml) and glacial acetic acid (0.5 ml) are added to a mixture of Pd(OH)<sub>2</sub>/C (Pearlman catalyst, Pd content 20%, 0.028 g) and the benzyl ether **31** (0.048 g, 0.047 mmol). The flask is evacuated and flushed with argon several times. It is then

flushed with hydrogen, and the black reaction mixture is hydrogenated under a slightly elevated pressure of hydrogen at room temperature for 17 hours and then filtered through a cellulose filter (pore size 45  $\mu\text{m}$ ). The filtrate is concentrated in vacuo, and the residue is taken up with water and concentrated again several times in order to remove excess acetic acid. A solution of the residue in water is passed through a Dowex50 ion exchange column ( $\text{Na}^+$  form, diameter of the column 0.9 cm, length 3.5 cm) washing with deionized water. The clear filtrate is concentrated in vacuo and purified by gel filtration on Bio-Gel P2 (particle size 65  $\mu\text{m}$ , column diameter 2.5 cm, length 35 cm, eluent: water, flow rate 0.45 ml/min, detection at 230 nm) and subsequent reverse phase chromatography (Merck RP18 silica gel, elution with 7:3  $\text{H}_2\text{O}$ /methanol), resulting in the target molecule **B1.39** (0.014 g, 51 %) as a fluffy white solid (after lyophilization):  $^1\text{H}$  NMR (400 MHz,  $\text{D}_2\text{O}$ )  $\delta$  4.83 (d,  $J=4.0$  Hz, 1H), 4.49 (q,  $J=6.6$  Hz, 1H), 4.33 (d,  $J=7.7$  Hz, 1H), 3.74 (d,  $J=3.1$  Hz, 1H), 3.22 (dd,  $J=2.6, 9.5$  Hz, 1H);  $^{13}\text{C}$  NMR (100.6 MHz,  $\text{D}_2\text{O}$ )  $\delta$  181.5 ( $\text{C}_9$ ), 100.2 (CH), 95.7 (CH); MS (FAB, THG) 609 ( $\text{M}+\text{Na}$ ), 587 ( $\text{M}+\text{H}$ ).

**Example B21: Preparation of compound B1.41**

The hydroxypiperidine (6.0 g, 34.6 mmol, prepared from D-(–)-lyxose in accordance with Ichikawa and Igarashi [Ichikawa, Y., Igarashi, Y., *Tetrahedron Letters* 36:4585-4586 (1995)] and triethylamine (18.1 ml, 130 mmol) are dissolved in dry tetrahydrofuran (100 ml) and the solution is cooled to  $-10^\circ\text{C}$  under an argon atmosphere. Allyl chloroformate (3.87 ml, 36.4 mmol) is slowly added over the course of one hour, a white suspension being formed. The reaction mixture is stirred at  $-10^\circ\text{C}$  for a further hour, then 1M aqueous  $\text{KH}_2\text{PO}_4$  solution (150 ml) is added, and the mixture is extracted three times with  $\text{CH}_2\text{Cl}_2$ . The combined organic phases are dried ( $\text{Na}_2\text{SO}_4$ ) and concentrated in vacuo, resulting in a yellow oil (9 g). Purification by column chromatography on silica gel (hexane/ethyl acetate 1:1) results in the allyl carbamate **34** (7.66 g, 86 %).

4Å molecular sieves (dried under high vacuum at 300°C, 15 g) are added to a solution of the acceptor 34 (7.66 g, 29.8 mmol) in dry  $\text{CH}_2\text{Cl}_2$  (150 ml) under an argon atmosphere, and the suspension is stirred at room temperature for one hour. In parallel with this, a suspension of DMTST (15.4 g, 59.6 mmol) and 4Å molecular sieves (15 g) in dry  $\text{CH}_2\text{Cl}_2$  (150 ml) is prepared under an argon atmosphere in a second round-bottom flask and is stirred for one hour. The DMTST mixture is then added in 4 portions over the course of a further hour to the solution of the acceptor, and the mixture is then stirred for one hour. The reaction mixture is filtered through Hyflo Super Cel® washing thoroughly with  $\text{CH}_2\text{Cl}_2$ . The filtrate is extracted by shaking with 10% aqueous  $\text{NaHCO}_3$  solution, the aqueous phase is reextracted three times with  $\text{CH}_2\text{Cl}_2$ , and the combined organic phases are dried ( $\text{Na}_2\text{SO}_4$ ), filtered and concentrated in vacuo. The remaining yellow oil (36 g) is purified by column chromatography on silica gel (gradient elution: hexane/ethyl acetate 3:1 to 3:2), resulting in the glycoside 35 (13.1 g, 54 %).

The acetonide 35 (13.1 g, 15.94 mmol) is dissolved in dioxane (140 ml) and, at room temperature 50 % aqueous trifluoroacetic acid (250 ml) is added. After 2 hours, the reaction mixture is concentrated under high vacuum, and the residue is purified by column chromatography on silica gel (ethyl acetate/hexane 2:1), resulting in the diol 36 (11, 23 g, 90 %).

- 75 -

A mixture of the diol 36 (11.63 g, 14.88 mmol), tetra-*n*-butylammonium bromide (12.7 g, 39.4 mmol) and 4Å molecular sieves (dried under high vacuum at 300°C 22 g) is dried under high vacuum for 30 minutes and then, under an argon atmosphere, dry CH<sub>2</sub>Cl<sub>2</sub> (62 ml) and dimethylformamide (36 ml) are added. The grey suspension is stirred at room temperature for 30 minutes. In parallel with this, a solution of ethyl -2,3,4-tri-*O*-benzyl-1-thio-L-fucopyranoside (7.48 g, 15.62 mmol, prepared by the method of Lonn [Lonn, H. Carbohydr. Res. 139:105-113 (1985)] in dry CH<sub>2</sub>Cl<sub>2</sub> (49 ml) is prepared under an argon atmosphere in a second round-bottomed flask and, at 0°C, a bromine solution (2.85 g Br<sub>2</sub>, 17.84 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (25 ml) is added. The red solution is stirred at 0°C for 30 minutes, and the excess bromine is destroyed by adding a few drops of cyclohexene. This solution is then added using a needle to the solution of the acceptor, and the reaction mixture is stirred at room temperature for 40 hours. The reaction mixture is then filtered through Hyflo Super Cel® and thoroughly washed with CH<sub>2</sub>Cl<sub>2</sub>, and the filtrate is washed with 10 % aqueous NaHCO<sub>3</sub> solution. The aqueous phase is reextracted three times with CH<sub>2</sub>Cl<sub>2</sub>, and the combined organic phases are dried (Na<sub>2</sub>SO<sub>4</sub>), filtered and concentrated in vacuo. The residue is purified by column chromatography on silica gel (ethyl acetate/hexane 35:65), with the required product 37 (7.85 g, 44 %) being eluted.

The reaction mixture is heated to 35 to 40°C and stirred at this temperature for 3 hours. Then a solution of 15% KF in 1M aqueous KH<sub>2</sub>PO<sub>4</sub> solution (100 ml) is added, and the mixture is extracted three times with CH<sub>2</sub>Cl<sub>2</sub>, and the combined organic phases are dried (Na<sub>2</sub>SO<sub>4</sub>), filtered and concentrated in vacuo. The oily residue

The filtrate is concentrated in vacuo, and the residue is taken up with water and concentrated again several times in order to remove excess acetic acid. A solution of the residue in water is passed through a Dowex50 ion exchange column ( $\text{Na}^+$  form, diameter of the column 0.9 cm, length 3.5 cm) washing with deionized water. The clear filtrate is concentrated in vacuo and purified by gel filtration on Bio-Gel P2 (particle size 65  $\mu\text{m}$ , column diameter 2.5 cm, length 35 cm, eluent: water, flow rate 0.45 ml/min, detection at 215 nm) and subsequent reverse phase chromatography (Merck RP18 silica gel, gradient elution:  $\text{H}_2\text{O}$ /methanol 65:35 to 55:45), resulting in the target molecule **B1.41** (0.014 g, 59 %) as a fluffy white solid (after lyophilization):  $^1\text{H}$  NMR (500 MHz,  $\text{D}_2\text{O}$ , +50°C)  $\delta$  7.58 - 7.53 (m, 4H), 7.51 - 7.46 (m, 1H), 5.22 (d,  $J=4.0$  Hz, 1H), 4.57 (d,  $J=7.6$  Hz, 1H), 4.56 (q,  $J=6.4$  Hz, 1H), 4.33 (dd,  $J=4.2, 8.6$  Hz, 1H), 4.30 (dt,  $J=6.3, 3.2$  Hz, 1H), 3.66 (dd,  $J=8.0, 9.4$  Hz, 1H), 3.59 (dd,  $J=3.0, 13.8$  Hz, 1H), 3.33 (dd,  $J=4.2, 14.0$  Hz, 1H), 3.13 (dd,  $J=9.0, 14.0$  Hz, 1H), 1.82 (sex,  $J=6.9$  Hz, 2H), 1.36 (d,  $J=6.4$  Hz, 3H), 1.10 (t,  $J=7.5$  Hz, 3H); MS (FAB, NBA) 720 ( $\text{M}+\text{Na}$ ), 698 ( $\text{M}+\text{H}$ ).

ted in vacuo. The crude product (4.5 g) is purified by column chromatography on silica gel (eluent:  $\text{CH}_2\text{Cl}_2$ /methanol 19:1) to give the triol **54** (2.89 g, 92 %).

A suspension of **54** (2.89 g, 3.17 mmol) and di-*n*-butyltin oxide (1.56 g, 6.27 mmol) in dry benzene (95 ml) is boiled under reflux in an argon atmosphere for 16 hours. The reaction mixture is concentrated in vacuo and dried under high vacuum for one hour. Then CsF (dried under high vacuum at 300°C for several hours, 1.2 g, 7.9 mmol) is added under an argon atmosphere, followed by dry 1,2-dimethoxyethane (80 ml) and a solution of the triflate **A5** (6.3 g, 15.97 mmol) in dry 1,2-dimethoxyethane (50 ml). The reaction mixture is heated to 35 to 40°C and stirred at this temperature for 3 hours. The mixture is then washed with a solution of 15% KF in 1M aqueous  $\text{KH}_2\text{PO}_4$  (150 ml) and the aqueous phase is extracted three times with  $\text{CH}_2\text{Cl}_2$ , and the combined organic phases are dried ( $\text{Na}_2\text{SO}_4$ ), filtered and concentrated in vacuo. The oily residue (10.9 g) is purified by column chromatography on silica gel (elution: toluene/ethyl acetate 4:1, then  $\text{CH}_2\text{Cl}_2$ /methanol 19:1 to recover the precursor), resulting in the ether **55** (1.94 g, 53 %) as a colourless foam and partial recovery of the precursor (1.1 g, 26 %).

Morpholine (215  $\mu$ l) and  $\text{Pd}(\text{PPh}_3)_4$  (0.015 g, 0.013 mmol) are added under an argon atmosphere to a solution of the allyl carbamate 55 (0.15 g, 0.13 mmol) in tetrahydrofuran (1.7 ml). After exactly 15 minutes, the solution is concentrated and the residue is dried under high vacuum for one hour. The crude product is purified on a short silica gel column (eluent:  $\text{CH}_2\text{Cl}_2$ /methanol 19:1, contains 0.3 % concentrated aqueous ammonia solution) and then dried under high vacuum for one hour. The residue is then taken up in dry  $\text{CH}_2\text{Cl}_2$  (1.7 ml), the solution is cooled to  $0^\circ\text{C}$ , and triethylamine (43  $\mu$ l, 0.31 mmol) and *n*-butanesulfonyl chloride (18  $\mu$ l, 0.14 mmol) are added. After 15 minutes, the reaction mixture is warmed to room temperature and washed with 10 % aqueous  $\text{NaHCO}_3$  solution. The aqueous phase is reextracted three times with  $\text{CH}_2\text{Cl}_2$ , and the organic phases are combined, dried ( $\text{Na}_2\text{SO}_4$ ), filtered and concentrated in vacuo. Purification of the crude product by column chromatography on silica gel (eluent: ethyl acetate/hexane 30:70) gives the sulfonamide 56 (0.12 g, 77 %).

Dioxane (1.2 ml), water (0.6 ml) and glacial acetic acid (0.25 ml) are added to a mixture of  $\text{Pd}(\text{OH})_2/\text{C}$  (Pearlman catalyst, Pd content 20%, 0.035 g) and the benzyl ether 56 (0.027 g, 0.023 mmol). The flask is evacuated and flushed with argon several times. It is then flushed with hydrogen, and the black reaction mixture is hydrogenated under a slightly elevated pressure of hydrogen at room temperature for 12 hours and then filtered through a cellulose filter (pore size 45  $\mu\text{m}$ ). The filtrate is concentrated in vacuo, and the residue is taken up with water and concentrated again several times in order to remove excess acetic acid. The crude intermediate (0.017 g, lyophilized) is taken up in 1 M aqueous  $\text{NaHCO}_3$  solution (0.3 ml) and over the course of 5 hours, several small portions (30 bis 50  $\mu$ l) of an approx. 1 M solution of 3,4-dimethoxybenzoyl chloride in toluene are added, until a test by thin-layer chromatography (silica gel TLC plates, mobile phase: *n*-butanol/water/acetone/

glacial acetic acid/ $\text{NH}_4\text{OH}$  70:60:50:18:1.5) indicates complete conversion of the intermediate. The pH of the solution is kept basic during this reaction by adding several portions of solid  $\text{NaHCO}_3$  (about 0.025 g in total). The reaction mixture is then concentrated in vacuo, and the residue is taken up in a little water and purified by gel filtration on Bio-Gel P2 (particle size 65  $\mu\text{m}$ , column diameter 2.5 cm, length 35 cm, eluent: water, flow rate 0.45 ml/min, detection at 215 nm) and subsequent reverse phase chromatography (Merck RP18 silica gel, elution: methanol/ $\text{H}_2\text{O}$  65:35), resulting in the target molecule **B1.58** (0.008 g, 39 %) as a fluffy white solid (after lyophilization):  $^1\text{H}$  NMR (400 MHz,  $\text{D}_2\text{O}$ )  $\delta$  7.41 (br d,  $J=8.3$  Hz, 1H), 7.32 (br s, 1H), 7.04 (d,  $J=8.3$  Hz, 1H), 5.05 (d,  $J=3.9$  Hz, 1H), 4.51 (d,  $J=7.8$  Hz, 1H), 4.14 (q,  $J=6.7$  Hz, 1H), 4.09 (t,  $J=4.1$  Hz, 1H), 3.82 (s, 6H), 3.33 (dd,  $J=3.1, 9.6$  Hz, 1H), 1.13 (d,  $J=6.3$  Hz, 3H), 0.68 (t,  $J=7.6$  Hz, 3H); MS (FAB, THG) 923 ( $\text{M}+\text{Na}$ ), 901 ( $\text{M}+\text{H}$ ), 879 ( $\text{M}+2\text{H}-\text{Na}$ ).

Dioxane (5.3 ml), water (2.6 ml) and acetic acid (1.1 ml) are added to a mixture of  $\text{Pd}(\text{OH})_2/\text{C}$  (Pearlman catalyst, Pd content 20%, 0.13 g) and the benzyl ether **56** (0.12 g, 0.1 mmol). The flask is evacuated and flushed with argon several times. It is then flushed with hydrogen and the black reaction mixture is hydrogenated under a slightly elevated pressure of hydrogen at room temperature for 24 hours and then filtered through a cellulose filter (pore size 45  $\mu\text{m}$ ). The filtrate is concentrated in vacuo, and the residue is taken up with water and concentrated again several times in order to remove excess acetic acid. The crude amine (0.074 g) is taken up in a little water and purified by gel filtration on Bio-Gel P2 (particle size 65  $\mu\text{m}$ , column diameter 2.5 cm, length 35 cm, eluent: water, flow rate 0.45 ml/min, detection at 215 nm) and subsequent reverse phase chromatography (Merck

C. Ligand Binding Assay for Determination of IC<sub>50</sub> Values-conserved use of positive controls E-selectin/human IgG chimera [cloned and expressed according to Kolbinger et al.

Biochemistry 35:6385-6392 (1996)] are incubated in Falcon probind™ microtiter plate (Plate 1) at a concentration of 200 ng/well in 0.01 M Tris, 0.15 M NaCl, 1 mM CaCl<sub>2</sub>, pH 7.4 (Tris-Ca<sup>++</sup> buffer). Thus the plating solution is dispensed as 100 µl/well of 2 µg/ml E-chimera.

Row 12 is left blank with only buffer. Plate 1 is incubated covered at 37°C for 2 hours. After incubation 100 µl/well of 2 % BSA in Tris Ca<sup>++</sup> buffer is added and incubated at room temperature for 1 hour. During incubation the compounds (2x serial dilution) are titrated in 1 % BSA in Tris-Ca<sup>++</sup> using U-shaped low bind microtiter plates (Plate 2). The rows are serially diluted up to row 9. Rows 10, 11, and 12 are just buffer. Final volume is 60 µl/well and the first well contains 10 mM of compound with the exception of the positive controls, A (SLe<sup>x</sup>-Lemieux) and B are used as positive controls for each plate and the first well contains 5 mM of these compounds. PolySLe<sup>a</sup>SA-HRP conjugate is prepared in advance by incubating Sialyl Le<sup>a</sup>-PAA-biotin (cat #01-044, GlycoTech Corp., Rockville, MD) with Streptavidin-HRP in a molar ratio of 1:2. 60 µl/well of 1 ng/µl of polySLe<sup>a</sup>SA-HRP conjugate in 1 % BSA in Tris-Ca<sup>++</sup> are added to all wells except row 11 in Plate 2. Plate 1 is

washed four times with Tris- $\text{Ca}^{++}$  in the automatic plate washer. 100  $\mu\text{l}$ /well are transferred from Plate 2 to Plate 1 starting from lowest concentration of compound. Plate 2 is discarded. The plate is incubated while rocking at room temperature for 2 hours. The plate is washed 4 times with Tris- $\text{Ca}^{++}$  using automatic plate washer. 100  $\mu\text{l}$ /well of Substrate [Mix 3,3',5,5'-tetramethylbenzidine reagent and  $\text{H}_2\text{O}_2$ , at 1:1 ratio] are added with an 8 channel pipettor from right to left. The plate is incubated at room temperature for 2 minutes. The reaction is stopped by adding 100  $\mu\text{l}$ /well of 1M  $\text{H}_3\text{PO}_4$  using the 8 channel pipettor from right to left. Absorbance of light at 450nm is measured in a microtiter plate reader.

Control compound A:

Control compound B:

$\text{IC}_{50}$  is calculated by determining the concentration of compound required to inhibit maximal binding of the polySialylLe<sup>a</sup>HRP conjugate to immobilized E-selectin/human IgG chimera by 50%. The relative  $\text{IC}_{50}$  is calculated by determining the ratio of the  $\text{IC}_{50}$  of an internal control compound to the  $\text{IC}_{50}$  of the test compound.

In the following tables  $RIC_{50}$  means  $\frac{IC_{50}(\text{Test compound})}{IC_{50}(\text{Control compound A})}$
